2. METHODOLOGY

The beginning-of-month water levels for Lake Ontario were computed by use of a water level gage network located on the periphery of the lake. Ideally, these beginning-of-month levels should represent the instantaneous levels at the beginning of the months. Practically, however, representative instantaneous true water levels are difficult, if not impossible, to measure because of the effect of short-term fluctuations in wind speed and direction and changes in atmospheric pressure over very small time periods. These fluctuations could cause considerable error in computing a true instantaneous level for the lake. This error is lessened by specifying that the beginning-of-month level for each gage shall be equal to the average of the daily mean water levels of the first day of the month and the last day of the previous month.

The computations procedure was set forth by Quinn (1971) and consists of applying weighting factors to each water level gage in the network. The weighting factors were computed from Thiessen polygon networks drawn from the various water level gage networks. This is expressed mathematically as

$$L_o = W_1 L_1 + W_2 L_2 + W_3 L_3 + \dots + W_n L_n$$

for $W_1 + W_2 + W_3 + \dots + W_n = 1.0$

where L_o is the weighted Lake Ontario beginning-of-month water level,
 $L_1 - L_n$ are the beginning-of-month levels at the various gage locations,
 $W_1 - W_n$ are the Thiessen polygon weighting factors for gage locations, 1 to n,
n is the number of water level gages in the network.

The basic data used consist of daily mean water levels for the first and last days of the months for each water level gage in operation. These levels were computed from the gages by use of sampling rates varying from hourly values in the current period to tri-daily readings in the early nineteen hundreds. The gage response time of less than 1 minute is sufficient to filter out wind waves and ship effects but maintain the longer period variations. The water level gages used in the study, along with their period of study, are given in table 1, and their location is shown in figure 1. For this study the Burlington gage data are the combined data of the Hamilton gage which was discontinued at the end of 1970 and the nearby Burlington gage which starts in January 1971. Occasional missing gage data were interpolated from existing gages.

Table 1. Water Level Gages and Period of Study

Gage Location	Period of Study (daily means)
Oswego	1900 - Date
Toronto	1906 - Date
Kingston	1909 - Date
Cape Vincent	1916 - Date
Rochester	1953 - Date
Port Weller	1956 - Date
Cobourg	1956 - Date
Burlington	1961 - Date
Olcott	1967 - Date
Point Petre	1970 - Date

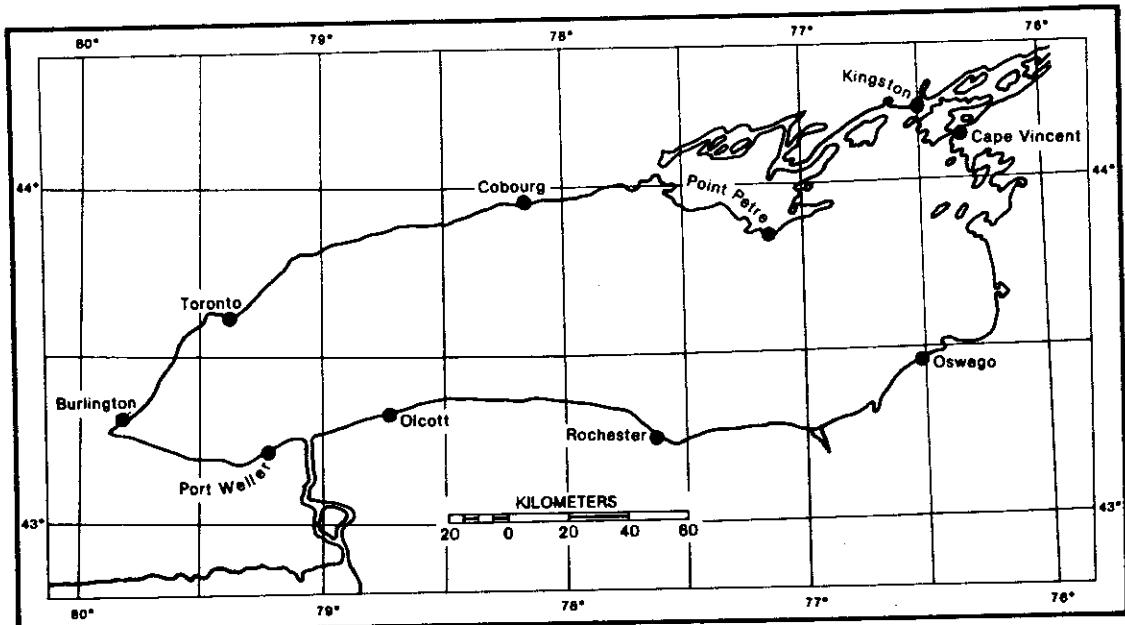

Figure 1. Water level gage locations.

In the initial analysis five different gage networks were developed for the 1950-1970 period to determine the optimum network size as well as to quantify a data set for this period. For obtaining a quantified data set for the 1900-1949 period, an additional three different gage networks were established. The Thiessen polygons shown on figures 2-5 were drawn and weighting factors computed for the gages in the various networks. These networks with their corresponding gages and weighting factors are given in table 2.

Burlington						0.028	0.028	0.028
Olcott							0.132	0.132
Point Petre								0.184

3. RESULTS

3.1 Effect of Gage Network Size

This analysis was based on 300 data points for each gage during the 1950-1974 period. The effect of the gage network size was investigated by comparing beginning-of-month lake levels computed by various sized networks during corresponding time periods. The statistical parameters used in the analysis were the standard deviation about zero, the mean, and the maximum of differences in beginning-of-month levels between two different sized networks. Data points were added to the 1953-1974 period to make it statistically compatible with the other periods. These additional points consisted of 5th, 10th, 15th, and 20th of month levels using the same procedure as the beginning-of-month levels. The results are presented in table 3.

The maximum deviation of -0.14 foot and standard deviation of 0.03 foot between the 9 and 10 gage networks results from the addition of the Point Petre gage. This gage has the highest weighting factor and represents a large portion of the lake area. Greater accuracy might be obtained by additional gages in the central portion of the lake.

3.2 Beginning-of-Month Levels

The beginning-of-month water levels computed for each gage are given in tables A.1-A.10 in the Appendix. Lake Ontario beginning-of-month levels, computed with the gage networks given in table 4, are presented in table A.11.

Table 3. Effect of Network Size on Beginning-of-Month Levels

Period	Networks Compared	Mean Dev.* (ft)	Std. Dev.* (ft)	Max. Dev.* (ft)
1950-1974	2 gage vs 3 gage	0.00	0.01	0.03
1950-1974	3 gage vs 4 gage	0.00	0.01	-0.06
1953-1974	4 gage vs 5 gage	0.01	0.02	0.05
1956-1974	5 gage vs 7 gage	0.00	0.02	0.06
1961-1974	7 gage vs 8 gage	0.00	0.01	-0.02
1967-1974	8 gage vs 9 gage	0.00	0.01	-0.03
1970-1974	9 gage vs 10 gage	0.01	0.03	-0.14

* Dev. = Deviation from corresponding beginning-of-month levels

Table 4. Gage Networks Used for Lake Ontario Beginning-of-Month Levels

Period	No. of Gages in Network	Period	No. of Gages in Network
1900-1905	1	1956-1960	7
1906-1908	2	1961-1966	8
1909-1915	3	1967-1969	9
1916-1952	4	1970-1974	10
1953-1955	5		

3.3 Change of Storage

The monthly changes in storage were computed by multiplying the difference between two consecutive beginning-of-month levels by the area of Lake Ontario, 7,340 square miles. The changes in storage were then converted into monthly rates by dividing by the number of seconds in each month. These rates of change are given in table A.12 expressed as thousands of cubic feet per second months (TCFS-months).

3.4 Crustal Movement Analysis

A crustal movement analysis was undertaken to determine relative rates of subsidence, if any, along the longitudinal lake axis, which coincides with the north-south lake orientation. The data used in the analysis consisted of yearly mean-water-level data for the period of study.

The analysis of relative movement along the longitudinal axis showed well defined movement between the Kingston and Oswego gages. As depicted in figure 6, the relative rate of movement between the two gages is 0.25 foot per 100 years.

4. CONCLUSIONS AND RECOMMENDATIONS

This study shows that the present gage network is adequate for both scientific and planning studies, but additional accuracy in beginning-of-month levels might be achieved by increasing the network size over the present level of 10 gages.

The beginning-of-month levels and storage changes listed in tables A.11 and A.12 are recommended for use in scientific and planning studies and should be updated on a yearly basis by the use of the Thiessen polygon procedure.
